Three children, two boys and a girl, were treated because of severe hyperammonemia and acidosis. The diagnosis was made by identifying the structural defect of carbonic anhydrase type IV (CA-IV) in cultured fibroblasts. Serum ammonia levels were constantly high (mean = 990 mumol/L). Results of a short-term treatment (ammonium acetate, 1500 mg/kg/day, i.v., for 4 days) were excellent in two patients, whereas the third patient showed no clinical improvement. The diagnosis of CA-IV deficiency was made in two patients by detecting low-activity CA-IV in cultured skin fibroblasts. The third patient showed no sign of CA-IV deficiency. Therapy with lactulose resulted in a remarkable decrease of plasma ammonia levels and led to a remarkable improvement of acidosis. Treatment was unsuccessful in one of the two patients. Urea cycle enzymes were elevated in plasma and liver, but activity of all these enzymes was significantly lower in cultured skin fibroblasts than in normal control skin fibroblasts. These patients had hyperinsulinism with inappropriately high insulin levels in the absence of growth hormone. Growth, intelligence, and activity scores were normal. Ammonia was the only factor responsible for their symptoms. Blood biochemistry and head computed tomography showed no pathological findings. Integration of a user-friendly software into the laboratory management of a test system. The article presents a software f988f36e3a
